Streamline lightspeed-stack config

To Do

Improve Feature

Key details

Field Tab Prioritization Release Testing SFDC Portfolio Solutions Business

Description

Feature Overview

Currently, the Lightspeed stack requires operators to manage two separate configuration files:

- `run.yaml` : For the underlying Llama Stack (e.g., inference endpoints, tools, vector stores).
- `lightspeed-stack.yaml` : For Lightspeed Core settings (e.g., authentication, data collection, server settings).

This dual-file system increases complexity and the potential for misconfiguration. This feature proposes merging all required settings into the primary lightspeed-stack.yaml. Lightspeed Core will be responsible for managing the necessary Llama Stack configuration from this single, unified source of truth.

The goal is to simplify the deployment and management experience for all downstream Lightspeed teams by providing a single, coherent configuration file.

Quickstart

We should evaluate the option of having the possibility of overriding the llama-stack configuration even in this single-config file model, to support some edge cases where Lightspeed teams need to configure the underlying llama-stack directly.

Acceptance criteria

- All necessary configurations required for Lightspeed assistants to operate previously set in run.yaml can now be defined within the lightspeed-stack.yaml file.
- Lightspeed Core correctly parses the unified configuration and applies the appropriate settings to the underlying Llama Stack services at runtime.
- The need for downstream teams to manually create or modify a separate run.yaml is completely eliminated.
- The stack deploys and operates correctly using only the single lightspeed-stack.yaml file.
- All relevant documentation is updated to reflect the new, single-file configuration process.
